Abstract:
This study was conducted to measure serum levels of plasma lipids (TG, TC, HDL-c and LDL-c) in patients with chronic renal failure. Seventy five random samples were collected from patients were already attended ALnaw Teaching Hospital during the period between January to march 2015 chosen randomly and seventy five apparently healthy individuals were selected as controls.

Enzymatic method was used to estimate serum lipid profile levels manually using Biosystem kits and by using Mindary, and results were analyzed using (SPSS) computer program (T-test and ANOVA test).

The results showed that serum levels of TG, TC, and LDL were significantly increased (p-value = .000) (p-value = .001) (p-value = .000) respectively and the serum levels of HDL were significantly decreased (p-value = .000) in the Sudanese patients group.

¹ Corresponding author: nuhabubkr@gmail.com
TG serum level increased between (101.5±35.8) in control to (132.2±56.3) in patients. TC also increased to (138.0±42.0) compared to control (121.6±23.0). LDL showed the same pattern and significantly increased to (133.8±43.1) in compare to control (92.8±37.8). HDL of patients decreased to (31.8±4.0) while in control was (37.0±5.4).

According to causes of renal failure the results of this study showed that; hypertension, diabetes and family history are the most common causes in Sudan.

The results of this study showed that there is a weak correlation between TG levels and duration of hemodialysis at (r = .223, p-value=.054). No correlation between TC (r=.166, p-value =.154), HDL-c (r=.166, p-value =.156) and LDL-c (r=.133, p-value =.254) levels and duration of dialysis was observed.

In conclusion: the serum levels of TG, TC, and LDL significantly increased in Sudanese patients with renal failure, but serum levels of HDL significantly decreased in patients subjected them to risk of many complications.

INTRODUCTION

Kidneys are paired, bean shaped organs located retro-peritoneally on either side of spinal column.\(^{(1)}\) Macroscopically each kidney is enclosed by fibrous capsule of connective tissue, when dissected longitudinally; two region can be clearly discerned: the outer region called the cortex and the inner one is named medulla. The pelvis of the kidney is a basin like cavity at the upper end of the ureter into which newly formed urine passes.\(^{(2)}\)

Acute renal failure is a sudden sharp decline in renal functions due to acute toxic or hypoxic insults to the kidneys. Chronic renal failure is a clinical syndrome that occurs when there is gradual decline in renal functions over time.\(^{(1)}\)
are different types of kidney dialysis, including: Hemodialysis is most commonly used to treat people with end-stage kidney disease. Blood is filtered using a dialyzer and dialysis machine. During a hemodialysis session, your blood flows a little bit at a time through a special filter inside the machine. The filter removes wastes and extra fluids from your blood, but retains the proper balance of minerals such as potassium and sodium. Once the blood is cleaned, it is returned to the body.\(^{(3)}\)

Peritoneal dialysis is filtering blood inside the body after the abdomen is filled with a special cleaning solution. This method allows your blood to be cleaned while you sleep, while you work, or while you perform your everyday activities.

The major forms of plasma lipids are: Fatty acids which are straight chain carbon compounds of variety lengths, they are be saturated, mono unsaturated or poly unsaturated.

Triglycerides are molecules consist of one molecule of glycerol with three fatty acid molecules.

Phospholipids are polar, ionic lipids composed of 1.2 diacylglycerol and phosphodiester bridge link the glycerol back bone to some base usually nitrogenous such as choline, serine or ethanol amine.\(^{(4)}\) Cholesterol is saturated steroid of high molecular weight in it is esterifies form, it contain one fatty acid molecule. Lipoprotein are core of insoluble (non polar) cholesterol ester and triglycerides, surrounded by shell of protein, phospholipids and free cholesterol with their soluble (polar) group.\(^{(5)}\)

Dyslipidemia is a very common complication of chronic renal failure (CRF) and are actively participate in the deterioration of renal function. In Sudan feeding products which constitutes high amounts of calories beside low physical exercise are main factors which subjects Sudanese individuals to diseases as CRF.\(^{(6)}\)
MATERIAL AND METHODS

Study approach
A quantitative methods were used to measure plasma lipids (TG, TC, HDL-c and LDL-c) in Sudanese patients with renal failure in Khartoum state, during the period from January to March 2015.

Study area:
This study was conducted in Alnaw hospital in Khartoum state.

Target population:
The study included patients with renal failure (males and females) under hemodialysis.

Sample size:
A total of 75 patients with renal failure were enrolled in this study, plus (75) non patients apparently healthy volunteers' (age and sex matched with the test group) were included to serve as control.

Inclusion criteria:
Sudanese patients with renal failure and apparently healthy volunteers were included in this study.

Exclusion criteria:
Patients with renal failure and other disease that may affect the parameters under study were excluded from this study.

Ethical consideration:
Consent was taken regarding acceptance to participate in the study and reassurance of confidentiality. Before the specimen was collected, the donor knew that this specimen was collected for research purpose.
Data collection:
The Clinical data were obtained from history, clinical examination and hospital follow up records and were recorded on a questionnaire sheet.

Sample collection and processing:
About 2.5 ml of venous blood were collected from each participant (both cases and control). The samples collected under aseptic conditions and placed in sterile heparin containers, and after mixing centrifuged for 5 minutes at 3000 RPM to obtain plasma, then The obtained plasma were kept at -20°C till the time of analysis.

ESTIMATION OF TOTAL CHOLESTEROL

Principle of the method
Free and esterified cholesterol in the sample originates, by mean of the coupled reactions, acoloured complex that can be measured by spectrophotometry

\[
\begin{align*}
\text{Cholesterol ester} + \text{H}_2\text{O} & \quad \text{chol. esterase} \\
\text{Cholesterol} + \frac{1}{2} \text{O}_2 + \text{H}_2\text{O} & \quad \text{chol. oxidase} \\
2\text{H}_2\text{O}_2 + 4\text{-Aminoantipyrine+phenol} & \quad \text{Peroxidase} \\
& \quad \text{Quinoneimine} + 4 \text{H}_2\text{O}
\end{align*}
\]

Assay procedure:

<table>
<thead>
<tr>
<th></th>
<th>Blank</th>
<th>Standard</th>
<th>Sample</th>

</tr>
<tr>
<td>Sample</td>
<td>—</td>
<td>—</td>
<td>10 μL</td>
</tr>
</tbody>
</table>

The tubes were incubated for 10 minutes at room temperature, the absorbance of standard and sample were measured at 520 nm against the blank.
Calculations: The cholesterol concentration in the sample is calculated using the following general formula:

$$\frac{A_{\text{Sample}}}{A_{\text{Standard}}} \times C_{\text{Standard}} = C_{\text{Sample}}$$

Reference value:
- Up to 200 mg/dL desirable
- 200-239 mg/dL borderline high
- >240 mg/dL high

**ESTIMATION OF TRIGLYCERIDES**

**Principle of the method:**
Triglycerides in the sample originates, by means of the coupled reactions, a colored complex that can be measured by spectrophotometry

\[
\text{Triglycerides} + \text{H}_2\text{O} \xrightarrow{\text{Lipase}} \text{Glycerol} + \text{Fatty acids} \\
\text{Glycerol} + \text{ATP} \xrightarrow{\text{glycerol kinase}} \text{Glycerol-3-p} + \text{ADP} \\
\text{Glycerol-3-p} + \text{O}_2 \xrightarrow{\text{G-3-P-Oxidase}} \text{Dihidroxyacetone-P} + \text{H}_2\text{O}_2 \\
2\text{H}_2\text{O}_2 + 4\text{-Aminoantipyrine} + 4\text{-Cholesterol peroxidase} \xrightarrow{\text{Quinoneimine}} 4\text{H}_2\text{O}
\]

**Assay procedure:**

<table>
<thead>
<tr>
<th></th>
<th>Blank</th>
<th>Standard</th>
<th>Sample</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reagent (A)</td>
<td>1000 μL</td>
<td>1000 μL</td>
<td>1000 μL</td>
</tr>
<tr>
<td>Triglycerides standard(S)</td>
<td>—</td>
<td>10 μL</td>
<td>—</td>
</tr>
<tr>
<td>Sample</td>
<td>—</td>
<td>—</td>
<td>10 μL</td>
</tr>
</tbody>
</table>

The tubes were incubated for 15 minutes at room temperature, the absorbance of standard and sample were measured at 520 nm against the blank

Calculations: The triglyceride concentration in the sample is calculated using the following general formula:

$$\frac{A_{\text{Sample}}}{A_{\text{Standard}}} \times C_{\text{Standard}} = C_{\text{Sample}}$$

Reference value:
- Up to 150 mg/dL Normal
Effect of Hemodialysis on the Lipids Profile in Patients with Renal Failure - Khartoum State

150- 199 mg/dl  Borderline – high
>500 mg/dl  Very high

Estimation of HDL:

Principle of the method:
Very low density lipoproteins and low density lipoprotein in the sample precipitate with phosphotungstate and magnesium ions, the supernatant contains high density lipoproteins (HDL). The HDL Cholesterol is then spectrophotometrically measured by means of the coupled reactions described below

\[
\text{Cholesterol ester} + \text{H}_2\text{O} \xrightarrow{\text{chol esterase}} \text{Cholesterol} + \text{Fatty acid}
\]

\[
\text{Cholesterol} + \frac{1}{2} \text{O}_2 + \text{H}_2\text{O} \xrightarrow{\text{chol oxidase}} \text{Cholestenone} + \text{H}_2\text{O}_2
\]

\[
2\text{H}_2\text{O}_2 + 4\text{-Aminoantipyrine} + \text{phenol} \xrightarrow{\text{peroxidase}} \text{Quinoneimine} + \text{H}_2\text{O}_2
\]

\[
2\text{H}_2\text{O}_2 + 4\text{-Aminoantipyrine} + \text{phenol} \xrightarrow{\text{peroxidase}} \text{Quinoneimine} + 4\text{H}_2\text{O}_2
\]

Assay procedure

<table>
<thead>

</tr>
<tr>
<td>Sample supernatant</td>
<td>−</td>
<td>−</td>
<td>−</td>
</tr>
</tbody>
</table>

The tubes were mixed and incubated for 30 minutes at room temperature. The absorbance (A) of the standard sample were measured at 520 nm against the blank.

Calculations:
The HDL cholesterol concentration in the sample was calculated using the following general formula:

A sample/ A standard \times C standard \times sample dilution factor = C sample

Reference values:

</table>
Estimation of LDL

**Principle:** LDL precipitated by polyvinyl sulphate (buffered by poly-ethylene-glycol pH: 5.2) after centrifugation, chylomicrons, VLDL, HDL "other lipoproteins than LDL" are remain in supernatant and cholesterol of them estimated by cholesterol oxidase method, and after estimation of total cholesterol also, \( \text{LDL}_c \) calculated as follow:

\[
\text{LDL}_c = \text{Total cholesterol conc.} - \text{other lipoprotein cholesterol}
\]

**PROCEDURE:**

Step (1): precipitation of LDL:
In centrifuge tube add: 0.4mL from s/p +0.2 mL from polyvinyl sulphate of PEG
Mix, stand for 15' in R.T, then centrifuge for 10' at 4000 rpm, then obtain supernatant and continue as follow:

Step (2) estimation of other lipoproteins than LDL cholesterol:

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>Std</th>
<th>T</th>
</tr>
</thead>
<tbody>
<tr>
<td>working Reagent</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0ml</td>
</tr>
<tr>
<td>std (200mg/dL)</td>
<td>-</td>
<td>0.02</td>
<td>-</td>
</tr>
<tr>
<td>Supernatant</td>
<td>-</td>
<td>-</td>
<td>0.02 mL</td>
</tr>
</tbody>
</table>

Mix, incubate for 10' in room temperature then read at 520nm against reagent blank.

**Calculation**

Conc. of cholesterol of other lipoproteins than LDL = \[
\frac{A^0_T}{A^0 \text{ std}} \times \text{conc. of STD} \times \text{D.F.}
\]

D.F = 1.5

**R.V of LDL\(_c\)**

DISCUSSION

From the finding of this study it appears that that the majority of patients under dialysis participated in this study were in the average ages of about 55 years. This agreed with previous published results of many authors, whose finding confirmed that, after the age of 30 years, glomerular filtration rate (GFR) progressively declines at an average rate of 8 mL/min/173 m²
per decade, and the risk of renal failure increased with age. This result also was agreed with result carried by: (Christian)\textsuperscript{(8)} showed that the average age of a British person with the renal failure is 77 years. Sex distribution in patients under hemodialysis of this study revealed that 60\% were males. This agree with the previous study which documented in the field of nephrology, showed that women seem to be somewhat protected from developing end stage renal failure; the cumulative incidence of the disease remains low during the reproductive ages and begins to rise 10 years later\textsuperscript{(9)}.

Social clinical history index of patients under the study indicated that appositive family history of renal failure of first degree relatives found to be in 37\% of cases. These findings may indicate that hereditary play a role in the pathogenesis of renal failure patients. This result agreed with previous study showed that, There is a high prevalence of family history –end stage renal disease among US population, about 23\%.\textsuperscript{(10)} The findings of this study showed that, there was a significant differance in the body mass index (BMI; determined by dividing the weight in kilograms by the height in meter square.) between patients and control, the patients with renal failure susceptible to be more obese than control group. This made the BMI is independent factor of renal failure. This agreed with previous study which found positive correlation between increased (BMI) and risk of renal failure disease\textsuperscript{(11)}. Another study examined the relationship between increased weight (BMI) and renal function evaluated by the estimated glomerular filtration rate, Increased BMI was consistently associated with reduced glomerular filtration rate.\textsuperscript{(12)}

In this study serum levels of TG, TC, and LDL were significantly increased and the serum levels of HDL were significantly decreased in patients under hemodialysis group in compare to control group. TG (132.2±56.3 versus 101.5±35.8, p-
value = 0.00). TC (138.0±42.0 versus 121.6±23.0, P-value =0.001).
LDL (133.8±43.1 versus 92.8±37.8, p-value =0.00)
HDL (31.8±4.0 versus 37.0±5.4, p-value =0.00). This result agreed with a study carried by (Sathyian et al)(13), which showed that; Plasma TG, TC and LDL concentration frequently elevated in patients with CRF under hemodialysis because heavy proteinuria alone or in combination with chronic renal insufficiency results in acquired LDL receptor deficiency, which play a central role in the genesis of the associated hypercholesterolemia (Sathyian et al).(13)

Also the results was in agreement with another studies carried by many authors (Dipika et al)(6), (Weam)(14), (Nzere et al)(15), which finding confirmed that Chronic renal failure patients with hemodialysis are at greater risk of development of dyslipidemia characterized by hypertriglyceridemia, elevated TC and LDL-c levels and decreased HDL-c levels generated during the course of CRD which place them at risk of developing cardiovascular diseases.

According to figure (1) showed that, there was a weak correlation between TG levels and the duration of hemodialysis. this result disagreed with another result, which showed that, there was a strong correlation between TG levels and the duration of dialysis.(14)

Also the findings of this study showed that there were no correlation between duration of dialysis and concentration of TC, HDL-c and LDL-c as appeared in figure (2) (3) (4). This results agreed with previous results which revealed that no significant correlation between serum lipid profile levels and the duration of hemodialysis.(14)
